## Abstract

Michael Zoorob’s “Fentanyl shock: The changing geography of overdose in the United States” (2019) shows that geography and fentanyl exposure explain much of the variation in increased overdose mortality rates between 2011 and 2017. This paper succeeds in replicating all of the figures and tables in Zoorob’s research with the exception of Table 2B, the total estimated deaths attributable to fentanyl by each model. The estimates from table in the original publication more closely match official mortality statistics than the ones replicated in this paper. In addition to replicating Zoorob’s work, the extension of this paper aims to improve the two-stage least squares regression analysis by performing a *TBD* alternative strategy to analyze the instrumental variables. In my analysis I find  $X$ , which matters because  $Y$ .

## Introduction

Zoorob uses two models; Model 1 shows that fentanyl exposure has a positive association with mortality rates, and Model 2 tries to estimate the causal effect of fentanyl exposure on mortality rates. Zoorob runs a least squares regression for the first model. The model predicts overdose mortality as a function of fentanyl exposure. Fentanyl exposure takes into account the state, year, the natural logarithm of the number of test results containing fentanyl (in that state and year), and an error term. The standard errors are two-way clustered by state and year and includes population weights (Zoorob (2019)).

$$Overdose_{ij} = \alpha_i + \eta_j + \beta_1 Fentanyl_{ij} + \epsilon_{ij}$$

The second model uses a two-stage least squares regression:

$$\widehat{Fentanyl}_{ij} = \alpha_i + \eta_j + \beta_1 (Longitude_i \cdot Year_j) + \epsilon_{ij} \quad \widehat{Overdose}_{ij} = \alpha_i + \eta_j + \beta_2 \widehat{Fentanyl}_{ij} + \epsilon_{ij}$$

Findings in the paper show that much of the variation in the increased overdose mortality is explained by fentanyl exposure, and that fentanyl deaths are highly correlated with geography, as the epicenter of the overdose crisis has shifted towards the eastern U.S. They also found that longitude is better able to explain levels of overdose mortality over time. States east of the Mississippi River tend to have greater fentanyl exposure and sharper increases in overdose deaths than states west of the Mississippi River (Zoorob (2019)). Zoorob also uses both models to estimate the number of overdose deaths attributable to fentanyl and claims that they are broadly consistent with official mortality statistics.

Zoorob obtained the data used for his analysis through a Freedom of Information Act request. The data consist of state test results for drug seizures between 2011 and 2016, which he filters for test results containing fentanyl. Zoorob also uses age-adjusted mortality data from the National Center for Health Statistics. All the data used contain state and year information, and he uses state-annual populations to calculate mortality rates relative to a state’s population in a particular year. The data and code that Zoorob used in his paper is available on the Harvard Dataverse. To conduct my replication, I used R. More information on this project can be found on my Github repository.<sup>1</sup>

## Literature Review

### relevant literature in the paper

The number of drug overdose deaths in the United States has rapidly increased since 2014. However, the opioid epidemic did not affect all regions of the U.S. equally; according to the CDC, almost all states west of the Mississippi River did not see an increase while those to the west did. While Dasgupta et. al argue social and economic factors play a role in one's susceptibility to opioid addiction and overdose, Zoorob claims that the geographical patterns point to drug supply also playing a primary role in the epidemic.

### relevant literature since the paper published

Research by Barocas et al. on the effect of opioid use among patients with endocarditis cites Zoorob's paper and also finds a decreased risk of overdose associated with the West and South compared to the Northeast (Joshua A. Barocas (2020)). Although in 2018, drug overdose deaths actually decreased by 4.6% from 2017 in the United States, fentanyl deaths continued to rise ((*Drug Overdose Deaths*, n.d.))(Abby Goodnough (2019)). (Still looking for literature on this)

## Discussion

All of the figures and tables appear to be nearly the same, with a few exceptions. Firstly, the tables presented in the paper are of a different format than those produced by stargazer; I suspect the author might have just copied the information into a different table format in Excel for example for clarity (the values are all about the same). Secondly, Table 2 in the paper does not include the residual standard errors when presented in the paper, but I think maybe it should be? Finally, and perhaps most importantly, I see some differences between the small table after table one and this one provided in the paper:

<b>B: Total Estimated Deaths Attributable to Fentanyl by Model.</b>		
	<b>Model 1 Deaths</b>	<b>Model 2 Deaths</b>
<b>2011</b>	<b>2,295</b>	<b>2,705</b>
<b>2012</b>	<b>2,365</b>	<b>2,788</b>
<b>2013</b>	<b>3,312</b>	<b>3,904</b>
<b>2014</b>	<b>8,870</b>	<b>10,458</b>
<b>2015</b>	<b>15,446</b>	<b>18,211</b>
<b>2016</b>	<b>23,188</b>	<b>27,339</b>
<b>2017</b>	<b>30,398</b>	<b>35,841</b>

I will have to look into this further to see whether this is perhaps due to chance or the way I organized the code. The differences are not insignificant as some estimates are off by nearly 6,000 deaths.

## Extension

For my extension I am going to use an alternative regression method in place of model 2. Instead of two-stage least squares I am going to use \_\_\_\_\_ to analyze the instrumental variables.
